

## ACKNOWLEDGEMENT

First and foremost I thank the God Almighty for giving me the strength, knowledge, ability, opportunity to undertake this research work and to persevere and complete it successfully.

I extend my thanks to **Dr. (Mrs.) R. Nandini, Chairperson**, PSGR Krishnammal College for Women, Coimbatore for having given me the opportunity to undertake this research work in this esteemed institution..

I express my whole hearted thanks to **Dr. (Mrs.) N. Yesodha Devi, M.Com, M.Phil, Ph.D., Secretary**, PSGR Krishnammal College for Women, Coimbatore for her continuous motivation and encouragement.

My heartfelt thanks to **Dr. (Mrs.) S. Nirmala, MBA, M.Phil., Ph.D., Principal**, PSGR Krishnammal College for Women, Coimbatore for her kind support and for all the resources provided.

I place on record my deep sense of gratitude to my research supervisor **Dr. (Mrs.) M.S. Vijaya, M.Sc., M.Phil., Ph.D.**, Associate Professor and Head, Department of Computer Science, PSGR Krishnammal College for Women, Coimbatore for her sustained interest and advice that have contributed to a great extent to the completion of this work. I am thankful for her appropriate guidance, insightful suggestions and support in the completion of this research work. Her patience and immense knowledge has helped me during the tenure of research and writing of thesis.

I wish to thank my friend and research colleague **Mrs. K. Sathiyakumari** for her timely help and words of encouragement during the course of study. My sincere thanks to the faculty members of Department of Computer Science (PG) for their co-operation rendered.

Finally, I place on record my deep sense of gratitude to my beloved parents, husband, son, my sister and in-laws for supporting me in successfully completing this work. This would not have been possible without their unwavering and unselfish love and support given to me at all times.

**V.Pream Sudha**

## ABSTRACT

Globally an increasing number of children are being diagnosed with Autism Spectrum Disorder (ASD) and still more persons remain unidentified in the society. ASD is characterized by genetic heterogeneity and is defined by a range of conditions that affect persons to varied degrees. High risk factors for ASD include genes and genetic mutations, chromosomal conditions, family factors, prenatal influences and birth complications. Prediction of pretentious genes that underlie this disease is a significant challenge in biomedical research. This research titled “Deep Learning Framework For Efficient Prediction Of Causative Mutations, Genes And Their Susceptibility To Autism Spectrum Disorder” aims at predicting ASD causing genes, their susceptibility and contributing mutations by building models through user defined and self learned features based on conventional machine learning and contemporary deep learning approaches.

The core objectives of this research work are as follows.

1. To create a synthetic gene sequence database that mimics the causative ASD gene sequences
2. To identify and capture distinctive features from the diseased gene sequences that contribute to the classification of genes, their susceptibility to the disorder and the underlying mutations
3. To develop a framework based on conventional machine learning techniques for prediction of causative ASD genes and the underlying mutations
4. To develop a model to predict the susceptibility of the ASD genes to the disorder using supervised machine learning techniques
5. To build a deep learning framework for predicting the causative ASD genes, their vulnerability to the disorder and the driving mutations through user defined features
6. To employ Recurrent Neural Network (RNN) variants namely Bidirectional Recurrent Neural Network (BRNN), Long Short Term Memory (LSTM) and Gated Recurrent Units (GRU) with user defined features for creating computational models to predict ASD causing genes, their susceptibility and the driving mutations
7. To develop two kinds of encoding schemes namely codon encoding and one hot encoding to build DNN, BRNN, LSTM and GRU models through self-learned features for predicting ASD causative genes

The thesis explains a novel and an unprecedented approach wherein the problem of predicting ASD genes, their vulnerability to the disorder and the driving mutations are

formulated as pattern classification tasks and solved through conventional supervised learning and contemporary deep learning methods. These approaches simplify the prediction problem in generating reliable solution based on intelligent hints collected from simulated gene sequences.

Accurate prediction of ASD causing genes and mutations is a complicated task as the pattern of the gene sequence varies for every individual. As diseased gene sequences are not readily available, they are simulated with the gene mutational information collected from the Human Gene Mutational Database (HGMD). The genes associated with two kinds of ASD are examined and ten genes namely FMR1, MECP2, TSC1, CACNA1C, SHANK3, CHD8, FOXP2, CNTNAP2, GABRB3 and HOXA1 that are key players for syndromic and asyndromic ASD are considered for the study. The reference genes are identified from OMIM (Online Mendelian Inheritance in Man) database and its corresponding reference gene sequences are downloaded from NCBI. The raw sequence obtained from HGMD is processed to form cDNA sequence and the nucleotide base variation is done based on the mutational information obtained from HGMD database for four types of mutations namely Nonsense, Missense, Frameshift and Silent Mutations. The synthetic mutated gene sequences are generated and stored as fasta files. In each gene category 100 gene sequences are generated and a corpus comprising of 1000 synthetic gene sequences is developed.

The research work is carried out in three stages using conventional machine learning and the contemporary deep learning methods for building the predictive models.

In the first stage, the traditional learning approach is employed for building the prediction models and the key idea here is to identify and extract distinctive features from synthetic disease gene sequences. Various descriptors such as gene features, codon features, alignment features accounting to 43 attributes have been captured from 1000 gene sequences of 10 gene types and the dataset called Codon Measures Dataset (CMDS) is developed for learning the gene classification model. Mutational discriminators including gene mutation features, amino acid change features and published matrix features are identified and extracted. The dataset comprising 1000 instances with a dimension of 15 is created and named as Mutation Dataset (MDS) which is exploited for constructing the mutation recognition model. The cumulative strength of evidence for each ASD associated gene with attributes pertaining to gene, mutation, conserved protein domains, gene expression profiles and pathway interactions are integrated for all 1000 instances. A consolidated score is calculated by summing the various features for each individual variant of an ASD implicated gene leading to a clear understanding of their relevance to the disorder. Finally one of the

three class labels namely low(score < 0.5), medium (score  $\geq 0.5$  and < 0.8), high(score  $\geq 0.8$ ) is assigned to the gene depending on the range. Around 25 features have been captured from 1000 gene sequences of 10 gene types and the dataset called Gene Susceptibility Dataset (GSDS) is developed for the gene susceptibility identification model.

To predict the ASD candidate genes and mutations concurrently by classifying them based on the contributing features, a multi-dimensional machine learning approach is proposed. The profound association between genes and mutations is modeled as a multi-label problem by capturing the dependencies between them. The pooled mutation dataset (PMDS) with 58 features including codon measures and mutation features from 1000 instances is created by pooling the gene, mutations, amino acid substitution attributes and is used for multidimensional modeling of gene - mutation prediction problem. Min - max normalization is done to standardize the feature values of all the four datasets.

Various experiments are carried out by implementing supervised classification algorithms such as Decision tree, Multilayer Perceptron, Support Vector Machines using the above three dataset CMDS, MDS, GSDS in Scikit Learn environment and different independent data driven models are built correspondingly to identify 10 types of genes, to recognize 4 forms of mutations and to predict gene susceptibility. Multi-dimensional classifiers such as Bayesian classifier chains, Nearest Set Replacement, Class relevance, Ensemble of classifier chains with base classifiers are implemented using PMDS in MEKA environment and multi-dimensional models are built to predict the ASD candidate gene-mutation simultaneously.

In the second stage, the deep learning approach is employed for building the prediction models and the key idea here is to explore the competence of deep models. As deep architectures are able to discover the high-level features, detect complex interactions among them, increase interpretability and support variable-size data, they can be potentially powerful in discriminating ASD genes, their susceptibility and mutations. Initially, Deep Neural Network (DNN), architecture is attempted for learning feature representations, modeling their sequential dependencies and prediction. In the subsequent works, the variants of Recurrent Neural Network (RNN) namely Bidirectional Recurrent Neural Network (BRNN), Long Short Term Memory (LSTM) and Gated Recurrent Units (GRU) are employed to build the classifiers with user defined features and representation learning for the above mentioned tasks.

The deep learning experiments are carried out in Keras environment with Tensorflow as backend. The same three user defined feature sets with one hot encoded class labels are

used for training the above deep networks. Independent deep models are built correspondingly to identify 10 types of genes, to recognize 4 forms of mutations and to predict gene susceptibility.

In the last stage, two types of encoding schemes are proposed for deep learning and the key idea here is to utilize the self-learned features of deep learning models. The gene sequences are utilized as raw input data without any domain expertise and thereby the time consuming task of feature engineering is avoided. The first encoding scheme adopts codon encoding of diseased gene sequences and the Codon Encoded Dataset (CEDS) with 1000 instances of dimension 2582 is prepared. The next scheme uses one hot encoding technique wherein each input sequence is transformed into a 7746 x 4 one-hot encoded vectors and the One Hot Encoded Dataset (OHEDS) of 1000 samples is developed. DNN, BRNN, LSTM and GRU architectures are employed to build the ASD causative gene type identification model.

Various experiments have been carried out by implementing the above deep learning algorithms using Keras environment with Tensorflow as backend. The two encoded datasets with one hot encoded class labels are used for training the deep networks and independent deep classifiers are built to identify 10 types of genes.

The performances of all the predictive classifiers are evaluated using 10 fold cross validation and their effectiveness in recognizing the genes, mutations and in predicting the gene susceptibility with respect to various metrics like precision, recall, accuracy, F-measure is analyzed. The experimental results demonstrate that deep learning based GRU model is efficient in predicting the genes and mutations whereas LSTM model is competent in detecting the gene susceptibility. Also the experimental results proved that the GRU model utilizing the one hot encoded gene sequences is efficient in discriminating the ASD causing genes.

Identification of pretentious genes and mutations that underlie ASD is a significant challenge in biomedical research and hence an attempt is made to carry out research in this domain.
